1.2 Client-server-protocol

Messages between client and server are exchanged as strings.
Requests from client to server:

- getAvailableCollections
- getCollectionSize(collection)
- getCollection(String coll)
- getCollectionInRange(key, start, end)
- getCollectionInRangeSize(key, start, end)

Messages from server to client:

- ist of collections: String[]
- collection size: long
- data set: String[] // array of json records

1.3 Back-End

This subsection deals with the back-end of the ADIN INSPECTOR. How the system deals with client http calls, and how kafka interacts with the system. An overview of the system can be seen in Figure 1

1.3.1 Class Diagram

Next we'll look at each class and method in detail

- Config properties file
  The config file is stored alongside the built application .jar file and contains the path to the Kafka installation folder, the user name and password of a mongoDB account with the highest level of access and the name of the database.
- Initializer
  Methods:
  - main
    parameters: String of arguments from the console
    returns: void
    App entry point.
    We load the config.properties life and use the path provided to start the zookeper, kafka and mongodb services

- MongoConsumer
  The Mongo Consumer, as the name implies, consumes all messages from all topics in the Kafka messaging system. Once a message is found it is passed along to the Mongo Client for further processing.
  Variables
  - clientMediator
    Type : MongoClientMediator
    An instance of the Mongo Client Mediator, created with the credentials from the config file.

  Methods
  - MongoConsumer constructor
    parameters: user name and password of a mongoDB account with the highest level of access.
    returns: void
    Initializes the MongoClient variable and calls listenForRecords();
  - getAllTopics
    parameters: none
    returns: an array of strings containing all the available kafka records
    Asks the kafka server service which topics exists.
  - listenForRecords
    parameters: none
    returns: void
    This Method first calls getAllTopics and uses the array of topics to poll the kafka server for new messages.
    If new messages are found then the messages are passed to the Mongo Mediator for adding them to the Database.
    If no new messages are found for a topic notify the Mongo Mediator that the collection tied to the topic is ready for pre-processing.

- MongoClientMediator This object serves as a nexus between the users who want to get data out of the database and the consumer, and dataProcessor who want to add data into the database.
  Variables
  - client
    type: MongoClient
    An instance of the Mongo Client from the official java API.

  Methods
  - MongoClientMediator constructor
    parameters: Username and password
    returns: void
    Initializes the client variable, throws an error if the user is not found.

- addRecordToCollection
  parameters: String representation of a record in json format
  String name of the collection it should be added to.
  returns: void
  Converts the json string into a java object, then to a bson document and uses the mongoAPI to insert it into the database.
- addRecordsToCollection
  parameters: String Array of records to be added to a collection
  String name of the collection it should be added to.
  returns: void
  for each oneof the members of the array call addRecordToCollection
- ProcessCollection QUESTIONS FOR ANKUSH
  parameters: String, name of a collection
  returns: void
- getCollection
  parameters: String, name of a collection
  returns: String array containing all entries of the collection
- getStartRecord
  parameters: String, name of a collection
  returns: the first entry of the collection as a String.
- getEndRecord
  parameters: String, name of a collection
  returns: the last entry of the collection as a String.
- getCollectionSize
  parameters: String, name of a collection
  returns: the number of entries in the collectoin as int
- getCollectionInRange
  parameters: String, key of the parameter used for filtering
  String start and end ranges for the filtering
  returns: String array containing all entries of the collection within that range
  this Method is very general to allow for flexibility.For example by letting the key be, SourceIPaddresses, or a timeStamp.
- getCollectionInRange
  parameters: String, key of the parameter used for filtering
  String start and end ranges for the filtering
  returns: number of elements matching the range as int
  this Method is very general to allow for flexibility.For example by letting the key be, SourceIPaddresses, or a timeStamp.

- Record
  Every message that comes from kafka and needs to be added to the database has it's own Record class that inherit from this one.

Every single class that inherits needs to be able to, using reflection, convert itself into a Bson Document where every variable is a key Value pair of the name of the variable and it's associated value.
Variables

- id
  type: String

Methods

- getAsDocument()
  parameters: none
  returns: A Document, containing every variable of any class inheriting from this one.
  This function checks for every variable, gets it's name and value as a string and adds it to the document that it eventually returns.

- PacketRecord
  Inheriting from Record, this class contains the variables that match the json string obtained from kafka.
  Variables
  - id
    type: String
    this id is used for determining the ordering when saving to mongoDB, it's the offset of the message in the kafka messaging queue. inherited from Record
  - client
    type: String
  - L2Protocol
    type: String
  - SourceMACAddress
    type: String
  - L4Protocol
    type: String
  - SourceIPAddress
    type: String
  - PacketSummary
    type: String
  - DestinationIPAddress
    type: String
  - Timestamp
    type: String
  - DestinationPort
    type: String

- SourcePort
  type: String
- DestinationMACAddress
  type: String

Methods

- getters / setters
  parameters: none
  returns: variable type
  Each variable has it's getters and setter methods.

- AlarmRecord
  Variables
  - method
    An instance of the Mongo Client from the java API

  Methods
  - getters / setters
    parameters: none
    returns: variable type
    Each variable has it's getters and setter methods.

- AggregatedRecord
  Variables
  - method
    An instance of the Mongo Client from the java API

  Methods
  - getters / setters
    parameters: none
    returns: variable type
    Each variable has it's getters and setter methods.
