Contents

1 Front-End

This section describes the front-end of the ADIN INSPECTOR - the UI elements the GUI consists of, and how states are handled. A series of final UI design mockups are presented under UI Design Mockups section, whereas an overview of the GUI classes can be seen in Figure 8.

The GUI elements are implemented in React and Material UI, whereas the internal logic and application state management are written with MobX.

1.1 UI Design Mockups

An early stage interactive demo is available at `https://adin-frontend.netlify.com`.

1.3 Sequence Diagram

Figure 13: Sequence diagram of Login Authentication System. The user credentials are transmitted via https and the server returns a token to identify the following user session.
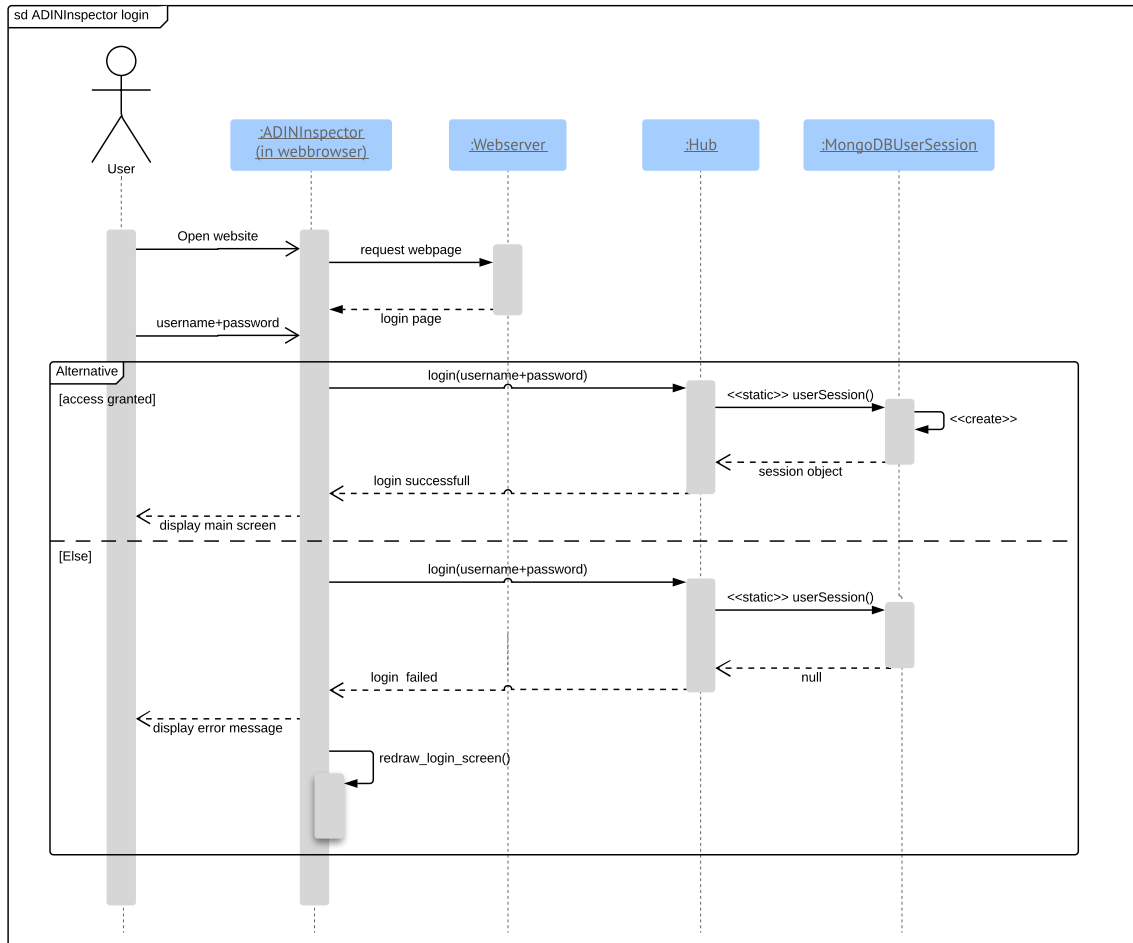

**ADIN Inspector
Client-Server-Communication: login**

Figure 14: This diagram shows an alternative view of the login sequence where the user credentials are transmitted via the same encrypted WebSocket connections which is used for the following session.
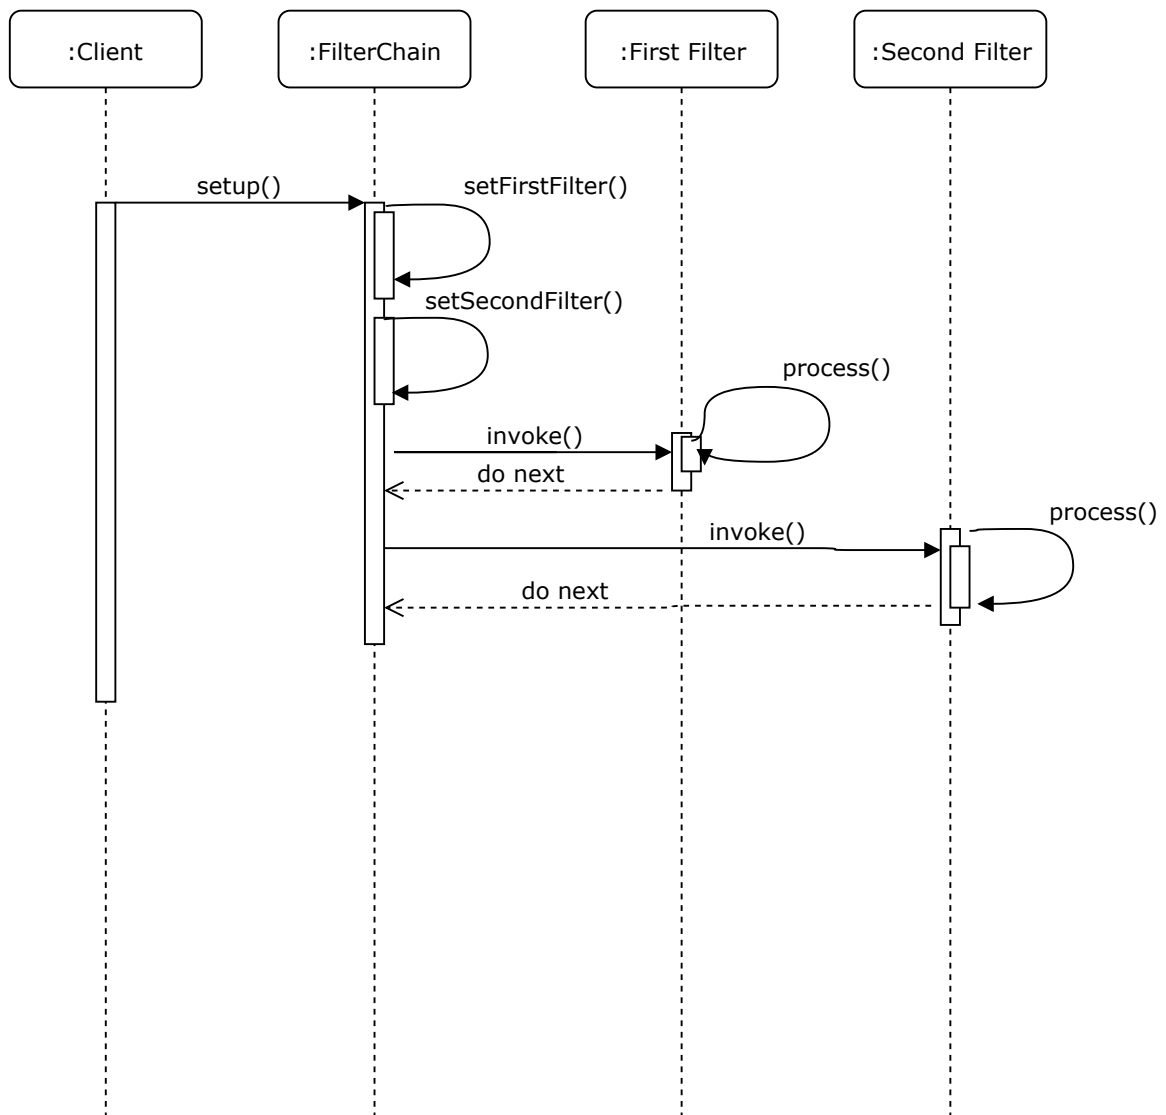

Figure 15: Sequence diagram of chaining filters in a specific diagram.

Figure 16: Selecting a specific option from a drop-down menu.
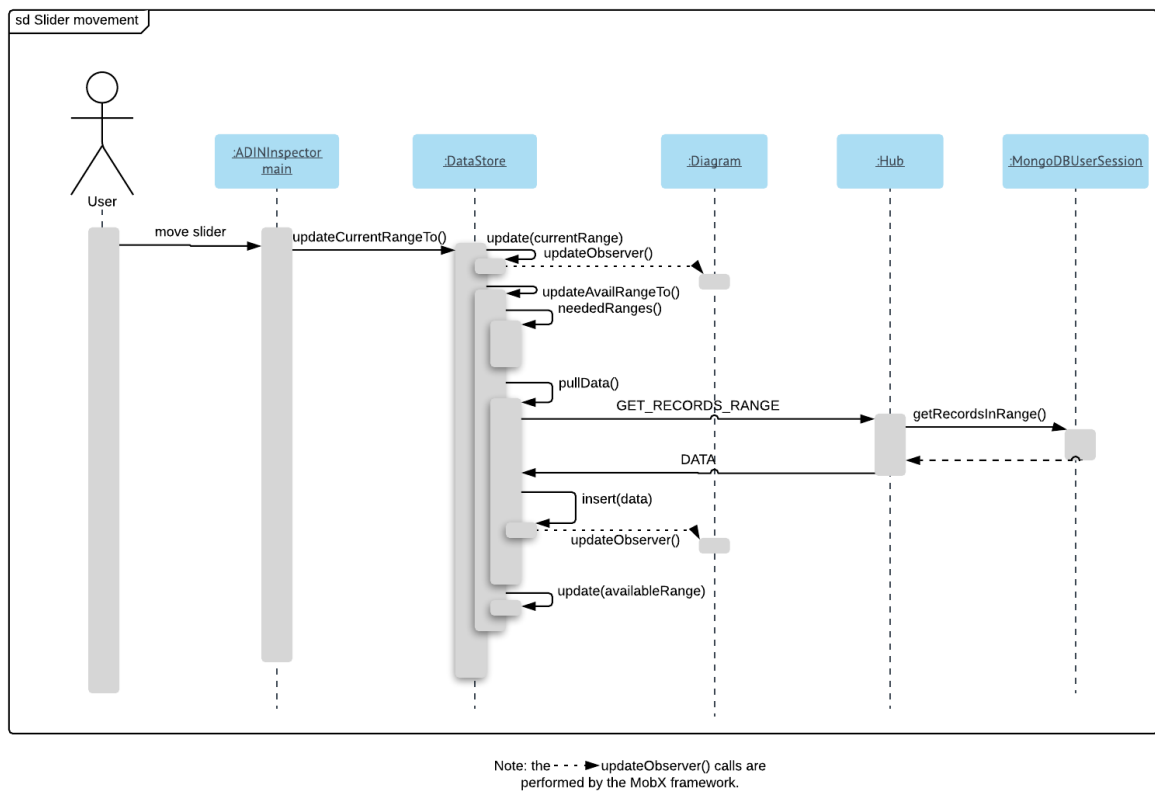

Figure 17: Sequence diagram showing control flow for handling a movement of the slider by the user.

2 Client-server protocol

The client (web browser) and server communicate using the encrypted WebSocket protocol (wss://). Messages between client and server are exchanged as strings in JSON format. Communication is typically initiated by the client. Each request has a message id which is echoed back in the response to help the sender to link the response to the request. The ids can be random, they don't have to be in a specific order.

By default, all requests apart from login will be ignored. A communication session starts with a login request that is responded to with an "OK" session control message. Within a communication session, login is ignored and all other requests can occur in arbitrary order. On receiving a logout request, the server returns into the default state, i.e logged out.

The user credentials that the user enters in the login web page can be transmitted in two different ways. In the first case they are sent via https with the POST method to the web server and the server returns a token which the client (the web browser) will save in a cookie and then transmit to the server in the WebSocket session with the LOGIN_TOKEN message to authenticate the WebSocket session (see Figure 13). In the alternative case the client opens an encrypted WebSocket connection to the server and sends the user credentials with the LOGIN message; i.e user authentication and data communication take place within the same WebSocket session (see Figure 14).

All communication, including the user authentication, uses https or wss, respectively, both of which use TLS/SSL encryption. The MongoDB data base doesn't store user passwords in plaintext but stores a hashed value derived from the password.

Responses carrying data, specifically "data set" and "collection size", will echo back any key-value pairs that are in addition to those specified in the protocol. This allows the client to add information that will help in processing the response, e.g. when requesting several "chunks" of data that will be concatenated.

In the following list words in angle brackets ("<>") are placeholders.

2.1 Requests from client to server:

- login
  syntax: {"cmd": "LOGIN", "user": "<username>", "pwd": "<password>", "id": "<id>"}
  expected response: session control with key "par" having the value "LOGIN"

- authentication via token
  syntax: {"cmd": "AUTH", "token": "<token>", "id": "<id>"}
  expected response: session control with "par": "AUTH"

- logout
  syntax: {"cmd": "LOGOUT", "id": "<id>"}
  expected response: session control with "par": "LOGOUT"

- getAvailableCollections
  syntax: {"cmd": "GET_AV_COLL", "id": "<id>"}
  expected response: list of collections

- getCollectionSize(collection)
  syntax: {"cmd": "GET_COLL_SIZE", "par": "<collection>", "id": "<id>"}
  where <collection> is the name of a collection
  expected response: collection size

- getStartRecord(collection)
  syntax: {"cmd": "GET_START", "par": "<collection>", "id": "<id>"}
  expected response: single data point, with "idx": "start" and key "data" containing the first data point of the given collection

- getEndRecord(collection)
  syntax: {"cmd": "GET_END", "par": "<collection>", "id": "<id>"}
  expected response: single data point, with "idx": "end" and key "data" containing the last data point of the given collection

- getEndpoints(collection)
  syntax: {"cmd": "GET_ENDPOINTS", "par": "<collection>", "id": "<id>"}
  expected response: data endpoints, with the key "data" containing a array consisting of the first and the last data point of the given collection

- getCollection(collection)
  syntax: {"cmd": "GET_COLL", "par": "<collection>", "id": "<id>"}
  expected response: data set

- getRecordsInRange(collection, key, start, end)
  syntax: {"cmd": "GET_RECORDS_RANGE", "par": "<collection>", "key": "<keyvalue>", "start": "<startvalue>", "end": "<endvalue>", "id": "<id>"}
  where <key> is the name of a key in the given collection and <startvalue> and <endvalue> are valid values for this key
  expected response: data set, where key "data" contains all data points (i.e. records) from the given collection for which the given key is in the interval [start, end).

- getRecordsInRangeSize(collection, key, start, end)
  syntax: {"cmd": "GET_RECORDS_RANGE_SIZE", "par": "<collection>", "key": "<key-value>", "start": "<startvalue>", "end": "<endvalue>", "id": "<id>"}
  expected response: collection size, where the key "par" gives the number of data points that would be returned by a getRecordsInRange() request with the same arguments.

2.2 Responses from server to client:

- session control
  syntax: {"cmd": "SESSION", "par": "<specifier>", "status": "<status>", msg": "<message>",
  "id": "<id>"}
  where <specifier> is one of "LOGIN", "AUTH", oder "LOGOUT", <status> is either "OK"
  or "FAIL" and <message> is a string, e.g. an error message
  "OK" as status for "LOGIN" and "AUTH" indicates a successful login, i.e. that the client
  session has started. "OK" as status for "LOGOUT" indicates that the server had ended the
  session and the user has been logged out.

- list of collections
  syntax: {"cmd": "LIST_COLL", "par": ["<collection>"], "id": "<id>"}
  where <collection> is the name of a collection

- collection size
  syntax: {"cmd": "COLL_SIZE", "name": "<name>", "key", "", "par": "<size>", "id": "<id>"}
  syntax: {"cmd": "COLL_SIZE", "name": "<name>", "key", "<key>", "start": "<start>", "end":
  "<end>", "par": "<size>", "id": "<id>"}
  where <name> is the name of a data collection and <size> is the number of data points
  in this collection . If <key> is not an empty string, then <size> will be the number of
  data points from the given collection for which the key value is in the interval [<start>,
  <end>).

- single data point
  syntax: {"cmd": "DATASINGLE", "name": "<collection>", "idx": "<idx>", "data": "<data>",
  "id": "<id>"}
  where <collection> is the name of a collection, "idx" has either the value "start" or "end",
  and <data> is a string representing a single data point in JSON format.

- data endpoints
  syntax: {"cmd": "DATA_ENDPOINTS", "name": "<collection>", "data": ["<start>", "<end>"],
  "id": "<id>"}
  where <collection> is the name of a collection and <start> and <end> are the first and
  last data point of this collection.

- data set
  syntax: {"cmd": "DATA", "name": "<name>", "key": "", "data": [<record>], "id": "<id>"}
  syntax: {"cmd": "DATA", "name": "<name>", "key": "<key>", "start": "<start>", "end": "<end>",
  "data": [<record>], "id": "<id>"}
  where <name> is the name of a data collection and each record is a JSON object describing
  a data point from this collection. If <key> is not an empty string, then the data array
  will contain those data points from the given collection for which the key value is in the
  interval [<start>, <end>).

3 Back-End

This section deals with the back-end of the ADIN INSPECTOR. How the system deals with client http calls, and how kafka interacts with the system. An overview of the system can be seen in Figure 21. Smaller sections have been expanded in Figure 18, Figure 19, Figure 20.

The connection to the client is handled in the class Hub which contains handlers for the network interface. This class uses a separate class (ClientProtocolHandler) to parse and handle requests from the handler. This setup is according to the strategy design pattern and allows easily modifying or even replacing the client server-protocol. The Hub class and the ClientProtocolHandler access the database via an object that implements the IUserSession interface and encapsulates the database session. Currently there is only an implementation for MongoDB access (MongoDBUserSession), but the abstraction via the IUserSession interface allows to add classes that offer access to Kafka or other databases. Classes that implement IUserSession are instantiated with a factory Method (UserSession()) which guarantees that the returned object represents a successfully logged in database session.

3.1 Class Diagram

The overview in Figure 21 shows a number of classes and their interaction with each other. What follows is a more in-depth view of what each component of this diagram does, what data it stores and how it fits into the overarching architecture.
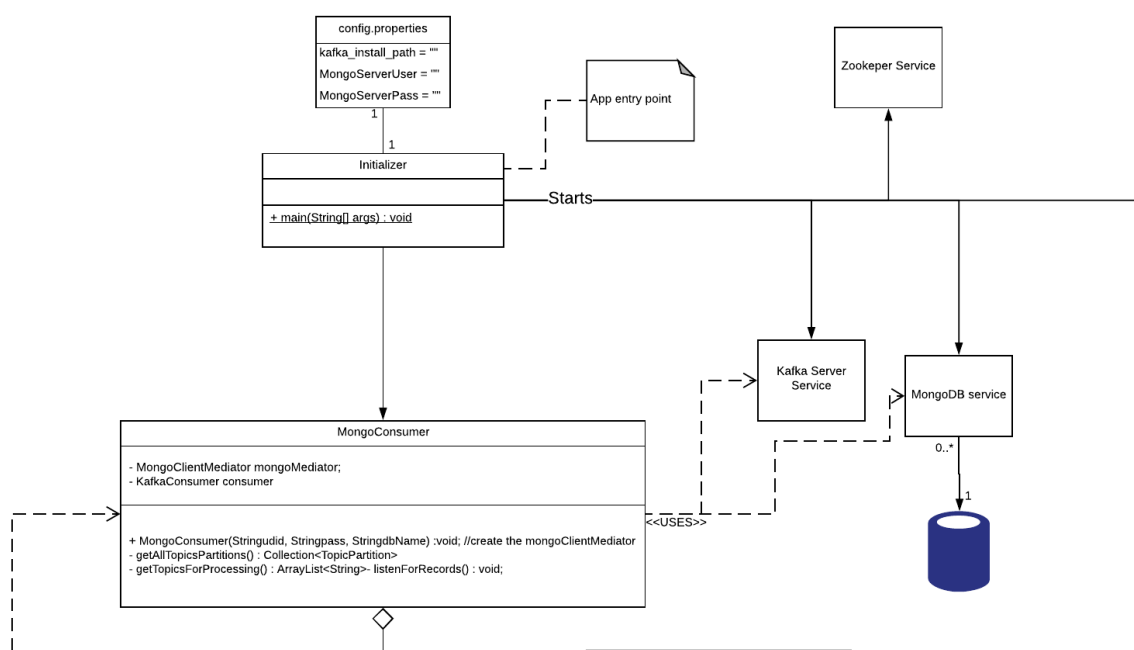

Figure 18: The classes involved in the initialization setup

- Config properties file
  The config file is stored alongside the built application .jar file and contains the path to the Kafka installation folder, the user name and password of a mongoDB account with the highest level of access and the name of the database.

- Initializer
  Methods:

    - main
      parameters: String of arguments from the console
      returns: void
      App entry point.
      We load the config.properties life and use the path provided to start the zookeeper, kafka and mongodb services

- MongoConsumer
  The Mongo Consumer, as the name implies, consumes all messages from all topics in the Kafka messaging system. Once a message is found it is passed along to the Mongo Client for further processing.
  Attributes

    - clientMediator
      Type : MongoClientMediator
      An instance of the Mongo Client Mediator, created with the credentials from the config file.

  Methods

- MongoConsumer constructor
  parameters: user name and password of a mongoDB account with the highest level of access.
  Initializes the MongoClient variable and calls listenForRecords();

- getAllTopics
  parameters: none
  returns: an array of strings containing all the available kafka Topics.
  Asks the kafka server service which topics exists.

- listenForRecords
  parameters: none
  returns: void
  This Method first calls getAllTopics and uses the array of topics to poll the kafka server for new messages.
  If new messages are found then the messages are passed to the Mongo Mediator for adding them to the Database.
  If no new messages are found for a topic notify the Mongo Mediator that the collection tied to the topic is ready for pre-processing.

- getTopicsForProcessing
  parameters: none
  returns: ArrayList<String>
  This convenience method returns a list of all topics to process, excluding internal Kafka topics and real-time data since the processing call is done elsewhere, as strings.
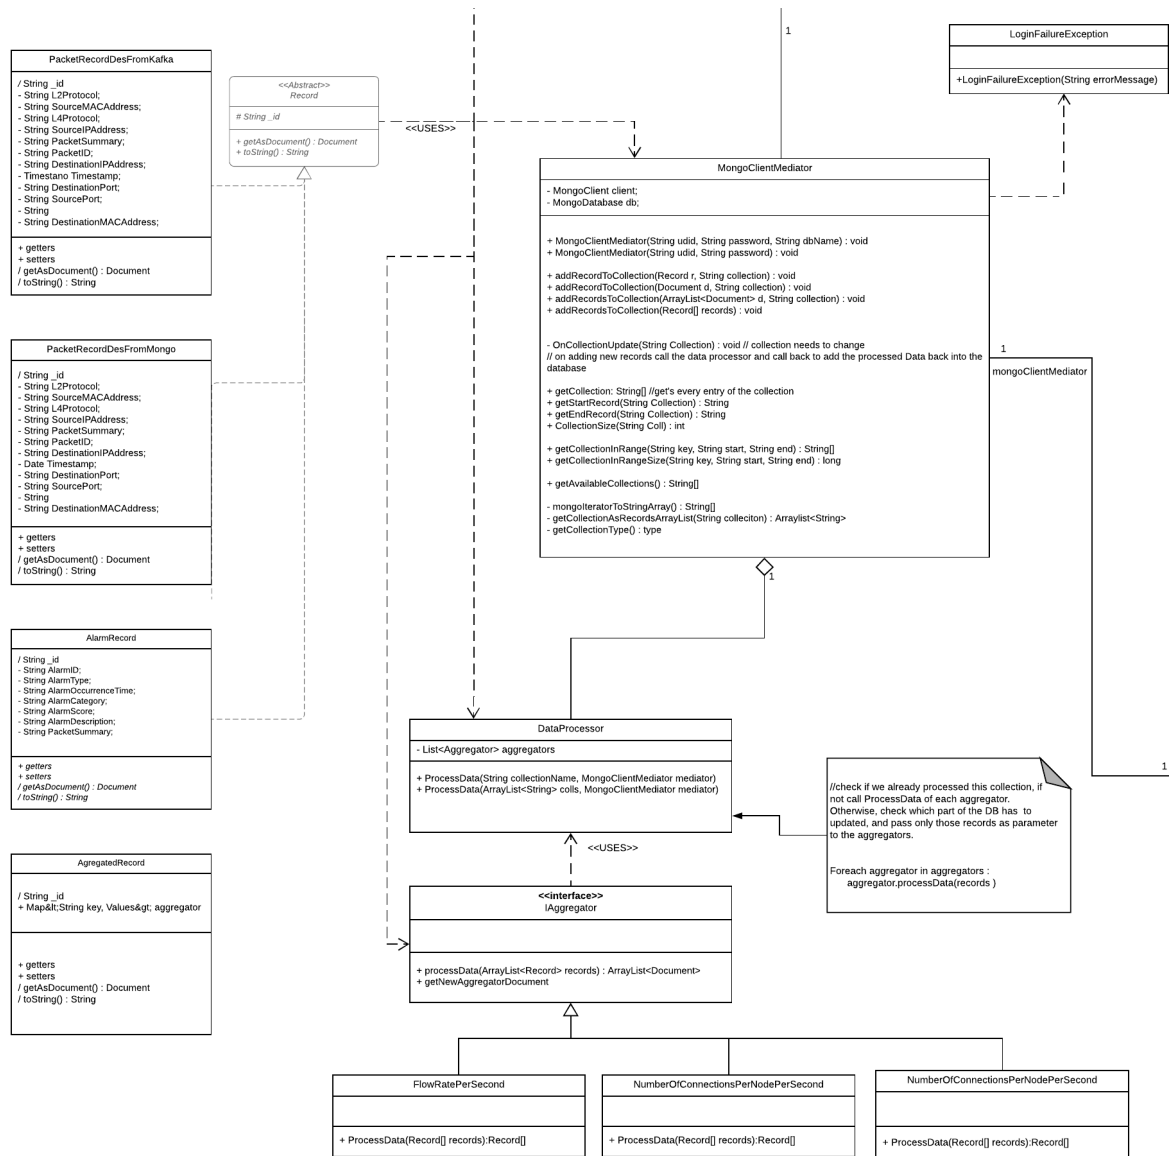

Figure 19: The classes involved in reading and writing data into the database

- MongoClientMediator This object serves as a nexus between the users who want to get data out of the database and the consumer and dataProcessor who want to add data into the database. This class encapsulates the mongo client from the mongo API. This means that any user wanting to sign in has to have valid credentials in the database, effectively relegating UAC to mongoDB.

  Attributes

    - client
      type: MongoClient
      An instance of the Mongo Client from the official java API.

    - dataProc
      A reference to the data processor class for this client.

  Methods

    - MongoClientMediator constructor
      parameters: Username and password
      Initializes the client variable, throws an error if the user is not found.

    - addRecordToCollection
      parameters: Record record - a record to add to the collection
      String collection - name of the collection it should be added to.
      returns: void
      Converts the record to a bson document and uses the mongoAPI to insert it into the database.

    - addRecordToCollection
      parameters: Document record - a record to add to the collection
      String collection - name of the collection it should be added to.
      returns: void
      Takes a bson Document containing a record and uses the mongoAPI to insert it into the database.

    - addRecordsToCollection
      parameters: Array of records - the records to be added to a collection
      String name of the collection it should be added to.
      returns: void
      for each oneof the members of the array call addRecordToCollection

    - addRecordsToCollection
      parameters: ArrayList of Documents - the records to be added to a collection
      String name of the collection it should be added to.
      returns: void
      for each oneof the members of the array call addRecordToCollection

    - ProcessCollection
      parameters: String, name of a collection
      returns: void
      signal the data processor to start the processing of a collection

- getCollection
  parameters: String, name of a collection
  returns: String array containing all entries of the collection

- getStartRecord
  parameters: String, name of a collection
  returns: the first entry of the collection as a String.

- getEndRecord
  parameters: String, name of a collection
  returns: the last entry of the collection as a String.

- getCollectionSize
  parameters: String, name of a collection
  returns: the number of entries in the collection as int

- getRecordsInRange
  parameters: String, name of the collection to query
  String, key of the parameter used for filtering
  String start and end ranges for the filtering
  returns: String array containing all entries of the collection within that range
  this Method is very general to allow for flexibility.For example by letting the key
  be, SourceIPaddresses, or a timeStamp.

- getRecordsInRangeSize
  parameters: String, name of the collection to query
  String, key of the parameter used for filtering
  String start and end ranges for the filtering
  returns: number of elements matching the range as int

- getRecordsInRange
  parameters: String, name of the collection to query
  Object, key of the parameter used for filtering
  Object start and end ranges for the filtering
  returns: String array containing all entries of the collection within that range
  this Method is very general to allow for flexibility.For example by letting the key
  be, SourceIPaddresses, or a timeStamp.

- getRecordsInRangeSize
  parameters: String, name of the collection to query
  Object, key of the parameter used for filtering
  Object start and end ranges for the filtering
  returns: number of elements matching the range as int

- getAvailableCollections
  parameters: -
  returns: String array with collection names
  Returns an array with the names of the collections available to the current user.

- Record
Every message that comes from kafka and needs to be added to the database has its own Record class that inherit from this one.
Every single class that inherits needs to be able to, using reflection, convert itself into a Bson Document where every variable is a key Value pair of the name of the variable and its associated value.
Attributes

  - id
  type: String

Methods

  - getAsDocument()
  parameters: none
  returns: A Document, containing every variable of any class inheriting from this one.
  This function checks for every variable, gets its name and value as a string and adds it to the document that it eventually returns.

- PacketRecordDesFromKafka
Inheriting from Record, this class contains the variables that match the json string obtained from kafka.
Attributes

  - L2Protocol
  type: String

  - SourceMACAddress
  type: String

  - L3Protocol
  type: String

  - L4Protocol
  type: String

  - SourceIPAddress
  type: String

  - PacketSummary
  type: String

  - DestinationIPAddress
  type: String

  - Timestamp
  type: Timestamp

  - DestinationPort
  type: String

  - SourcePort
  type: String

- DestinationMACAddress
  type: String

Methods

- constructor
  parameters: initializers for all attributes

- getters / setters
  parameters: variable
  returns: variable type
  Each variable has its getters and setter methods.

- PacketRecordDesFromMongo
  Inheriting from Record, this class contains the variables that match the json string obtained from kafka.
  Attributes

  - L2Protocol
    type: String

  - SourceMACAddress
    type: String

  - L3Protocol
    type: String

  - L4Protocol
    type: String

  - SourceIPAddress
    type: String

  - PacketSummary
    type: String

  - DestinationIPAddress
    type: String

  - Timestamp
    type: Date

  - DestinationPort
    type: String

  - SourcePort
    type: String

  - DestinationMACAddress
    type: String

  Methods

  - constructor
    parameters: initializers for all attributes

- getters / setters
  parameters: variable
  returns: variable type
  Each variable has its getters and setter methods.

- AlarmRecord
  Inheriting from Record, this class contains the variables that match the json string obtained from kafka.
  Attributes

  - id
    type: String

  - AlarmID
    type: String

  - AlarmType
    type: String

  - AlarmOccurrenceTime
    type: String

  - AlarmCategory
    type: String

  - AlarmScore
    type: String

  - AlarmDescription
    type: String

  - PacketSummary
    type: String

  Methods

  - getters / setters
    parameters: variable
    returns: variable type
    Each variable has its getters and setter methods.

- MiscRecord
  Inheriting from Record, this class is used by the data processor as an 'in-between' state before saving to the database. As well as an extension point for adding more types of records into the database programatically in the future.
  Refer to the data processor class for further data on the key value pairs.
  Attributes

  - pairs
    A Map of strings to Objects to store any 1 to many relationships

  Methods

  - getters / setters
    parameters: none
    returns: variable type
    Each variable has its getters and setter methods.

- DataProcessor
  This class is a mediator for each one of our data aggregators used for extraciton of features
  from the raw data stored in mongoDB.
  We might want to hve multiple data processors for chaining different aggregators together
  or to split up the work into mutliple threads. This is dependant on further performance
  testing.
  Attributes

  - client
    an instance of the associated mongoClient that requested the data aggregation

  - aggregators
    A Arraylist containing all the aggregators to be applied on a collection.

  Methods

  - getters / setters

  - processData
    parameters: variable
    returns: variable type

- IAggregator
  This interface is the building block for every aggregator to be applied to data
  Attributes Methods

  - processData
    parameters: Records array of the records to be processed

- FlowRatePerSecond
  Implements IAggregator. This calculates, per port, the outgoing and incoming connections.
  A record processed by this aggregator is stored in a collection as follows:

  ```
  Name of collection: collectionName\_FlowratePerSec
  structure of record as json:
   {
  "date" : \{" date" " Unix_Timestamp  }
  rounded down to the second this record points to.
  Connections : [
  { Port: "portNumer", "InOut" : " In/Out ", count : "Number" }
  { Port: "portNumer", "InOut" : " In/Out ", count : "Number" }

  ...

  ] This array has an entry per port if the port communicated that second.
  Precomputing this allows us to stream whenever the client needs the information
  ```

```
   for a specific node.
 }
```

Methods

- processData
  parameters: Records array of the records to be processed
  specific imlpementation left to the classes implementing this interface

- NumberOfConnectionsPerNodePerSecond
  Implements IAggregator. This calculates the outgoing and incoming connections. A
  record processed by this aggregator is stored in a collection as follows:

```
Name of collection: collectionName\_FlowratePerSec
structure of record as json:
 {
"date" : \{" date" " Unix_Timestamp  }
rounded down to the second this record points to.
Connections : [
{ Port: "portNumer", count : "Number" }
{ Port: "portNumer", count : "Number" }
...

] This array has an entry per port if the port communicated that second.
Precomputing this allows us to stream whenever the client needs the information
for a specific node.
}
```

Methods

- processData
  parameters: Records array of the records to be processed

- AddressesAndLinks
  Implements IAggregator. This aggregator produces a document containing a list of
  network nodes that show up in a collection and a list of connections between the nodes.
  Of importance is that nodes are unique while links do not have to be.

```
Name of collection: collectionName\_AddressesAndLinks
structure of record as json:
{
 "_id ": 0
"nodes"  :  [
{"id" : "MAC / IP / Port " , "type" : "L2/3/4" , "Protocol" : "Profinet/ Ethernet etc.
{"id" : "MAC / IP / Port " , "type" : "L2/3/4" , "Protocol" : "Profinet/ Ethernet etc.
...
]
```

```
 "links" : [
{"source" : "MAC / IP / Port " , "target" : "MAC / IP / Port "}
{"source" : "MAC / IP / Port " , "target" : "MAC / IP / Port "}
 ....
 ]
 }
```

Methods

- processData
  parameters: ArrayList records - the records to be processed
  returns: ArrayList<Document>

- LoginFailureException
  Exceptions of this class are thrown by MongoClientMediator and MongoClientConsumer when login into the mongo database was not possible; usually due to invalid username or password. Methods

  - constructor
    parameters: String errorMessage - the error message to be reported
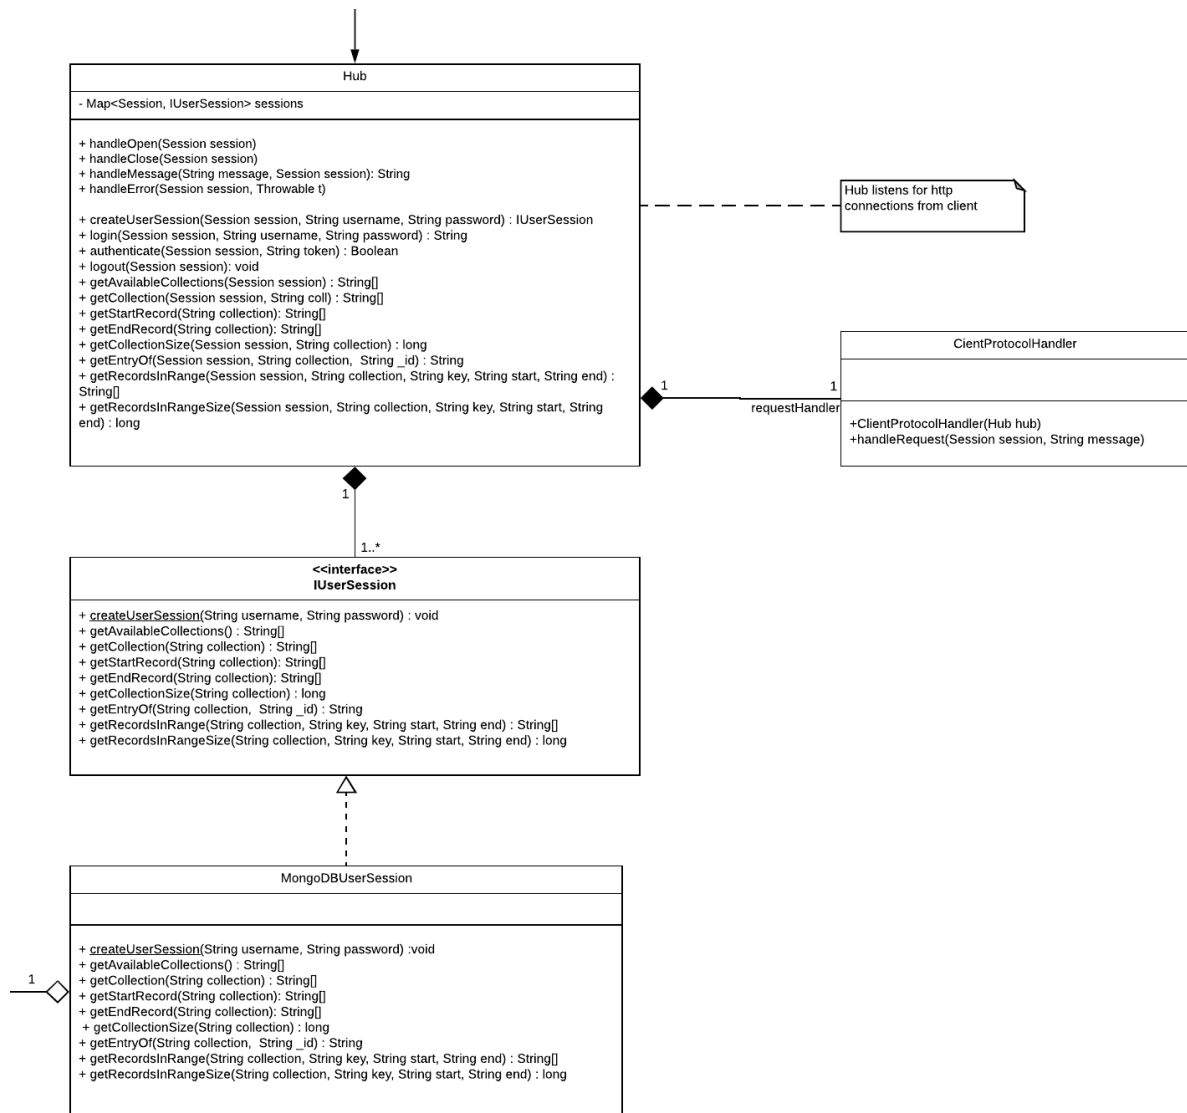

Figure 20: The classes involved in the communication between the server and the client

- Hub
  This class implements the network handlers for the WebSocket connection to the client. It also has wrapper methods that delegate the database commands to the appropriate IUserSession object.
  Attributes
  - requestHandler
    Type : ClientProtocolHandler
    The strategy object we call for the actual parsing of the client requests.

  - sessions
    Type : map<Session, IUserSession>
    A map that connects a client communication session to a database session. A non-null entry represents a successfully logged in user session.

  Methods
  - handleOpen
    parameters: Session session - the current session
    returns: void
    Event handler for the start of WebSocket connection.

  - handleClose
    parameters: Session session - the current session
    returns: void
    Event handler for closing a connection.

  - handleMessage
    parameters: String message - the message that we received from the client
    Session session - the current session
    returns: String - the response to be sent to the client
    Event handler for receiving a message. The message is passed to the ClientProtocol-Handler.

  - handleError
    parameters: Session session - the current session
    Throwable t - the exception that occurred
    returns: void
    Event handler for errors/exceptions during communication.

  - createUserSession
    parameters: Session session - the current session
    String username - the user id to login with
    String password - the password
    returns: IUserSession
    Delegate to the IUserSession method to instantiate a new UserSession and log in into the database using the given credentials.

  - login
    parameters: Session session - the current session
    String username - the user to log in

String password - the user's password
returns: String
If the username and password are valid, create a new database user session with the user logged in and return a authentication token. If the login fails, return an empty string.

- authenticate
  parameters: Session session - the current session
  String token - the authentication token to use
  returns: boolean
  Return true if this token corresponds to a valid, currently logged in user session, otherwise return false.

- logout
  parameters: Session session - the current session
  returns: void
  End the current session and log the user out.

- getAvailableCollections
  parameters: Session session - the current session
  returns: String array with collection names
  Returns an array with the names of the collections available to the current user.

- getCollection
  parameters: Session session - the current session
  String collection - name of a collection
  returns: String array containing all entries of the collection

- getStartRecord
  parameters: String, name of a collection
  returns: the first entry of the collection as a String.

- getEndRecord
  parameters: String, name of a collection
  returns: the last entry of the collection as a String.

- getCollectionSize
  parameters: Session session - the current session
  String collection - the collection to query
  returns: long - the number of records
  Returns the number of records in the specified collection.

- getRecordsInRange
  parameters: Session session - the current session
  String - name of the collection to query
  String key - the parameter used for filtering
  String start and end - range for the filtering
  returns: String array containing all entries of the collection within the filter range
  Returns an array containing all records of this collection for which the value of the

specified key is in the range [start, end). The records will be in the same order as they are in the collection.

- getRecordsInRangeSize
  parameters: Session session - the current session
  String - name of the collection to query
  String key - the parameter used for filtering
  String start and end - range for the filtering
  returns: number of elements matching the range as int
  Returns the number of records in the specified collection for which the value of the specified key is within the range [start, end).

- IUserSession
  An IUserSession object encapsulates a data base session. On instantiation an IUserSession connects to a database using the given user id and password and uses this connection for all following data base access.
  Methods

  - createUserSession
    parameters: String username - the user id to login with
    String password - the password
    returns: IUserSession
    Factory method to instantiate a new UserSession and log in into the database using the given credentials.

  - getAvailableCollections
    parameters: -
    returns: String array with collection names
    Returns an array with the names of the collections available to the current user.

  - getCollection
    parameters: String - name of a collection
    returns: String array containing all entries of the collection

  - getStartRecord
    parameters: String, name of a collection
    returns: the first entry of the collection as a String.

  - getEndRecord
    parameters: String, name of a collection
    returns: the last entry of the collection as a String.

  - getCollectionSize
    parameters: String collection - the collection to query
    returns: long - the number of records
    Returns the number of records in the specified collection.

  - getRecordsInRange
    parameters: String - name of the collection to query
    String key - the parameter used for filtering
    String start and end - range for the filtering
    returns: String array containing all entries of the collection within the filter range
    Returns an array containing all records of this collection for which the value of the specified key is in the range [start, end). The records will be in the same order as they are in the collection.

  - getRecordsInRangeSize
    parameters: String - name of the collection to query
    String key - the parameter used for filtering
    String start and end - range for the filtering
    returns: number of elements matching the range as int

Returns the number of records in the specified collection for which the value of the specified key is within the range [start, end).

- MongoDBUserSession
  Encapsulates a user session for a connection to a MongoDB database.
  Attributes

    - mongoClientMediator
      Type : mongoClientMediator
      The mediator object used to access the database

  Methods

    - MongoDBUserSession constructor
      parameters: -
      Private constructor to create a new MongoDB session.

    - createUserSession
      parameters: String username - the user id to login with
      String password - the password
      returns: a new MongoDBUserSession object
      Factory method to instantiate a new MongoDBUserSession and log in into the
      database using the given credentials.

    - getAvailableCollections
      parameters: -
      returns: String array with collection names
      Returns an array with the names of the collections available to the current user.

    - getCollection
      parameters: String - name of a collection
      returns: String array containing all entries of the collection

    - getStartRecord
      parameters: String, name of a collection
      returns: the first entry of the collection as a String.

    - getEndRecord
      parameters: String, name of a collection
      returns: the last entry of the collection as a String.

    - getCollectionSize
      parameters: String collection - the collection to query
      returns: long - the number of records
      Returns the number of records in the specified collection.

    - getRecordsInRange
      parameters: String - name of the collection to query
      String key - the parameter used for filtering
      String start and end - range for the filtering
      returns: String array containing all entries of the collection within the filter range
      Returns an array containing all records of this collection for which the value of the
      specified key is in the range [start, end). The records will be in the same order as
      they are in the collection.

- getRecordsInRangeSize
  parameters: String - name of the collection to query
  String key - the parameter used for filtering
  String start and end - range for the filtering
  returns: number of elements matching the range as int
  Returns the number of records in the specified collection for which the value of the specified key is within the range [start, end).

- ClientRequestHandler
  This class handles client requests by parsing them, executing the requested action and producing responses. The requested actions are typically executed by calls to the appropriate methods in the Hub object. The relation between the Hub class and this class is basically the strategy design pattern with a single strategy.
  Attributes

  - hub
    Type : Hub
    The Hub object to work with

  Methods

  - ClientRequestHandler
    parameter: Hub hub - the Hub object to work with
    The constructor; sets the hub attribute.

  - handleRequest
    parameters: Session session - the current client session
    String message - the client request to process
    returns: String - the response to be sent to the client
    Parse the message from the client, execute the requested action, and construct the response message.
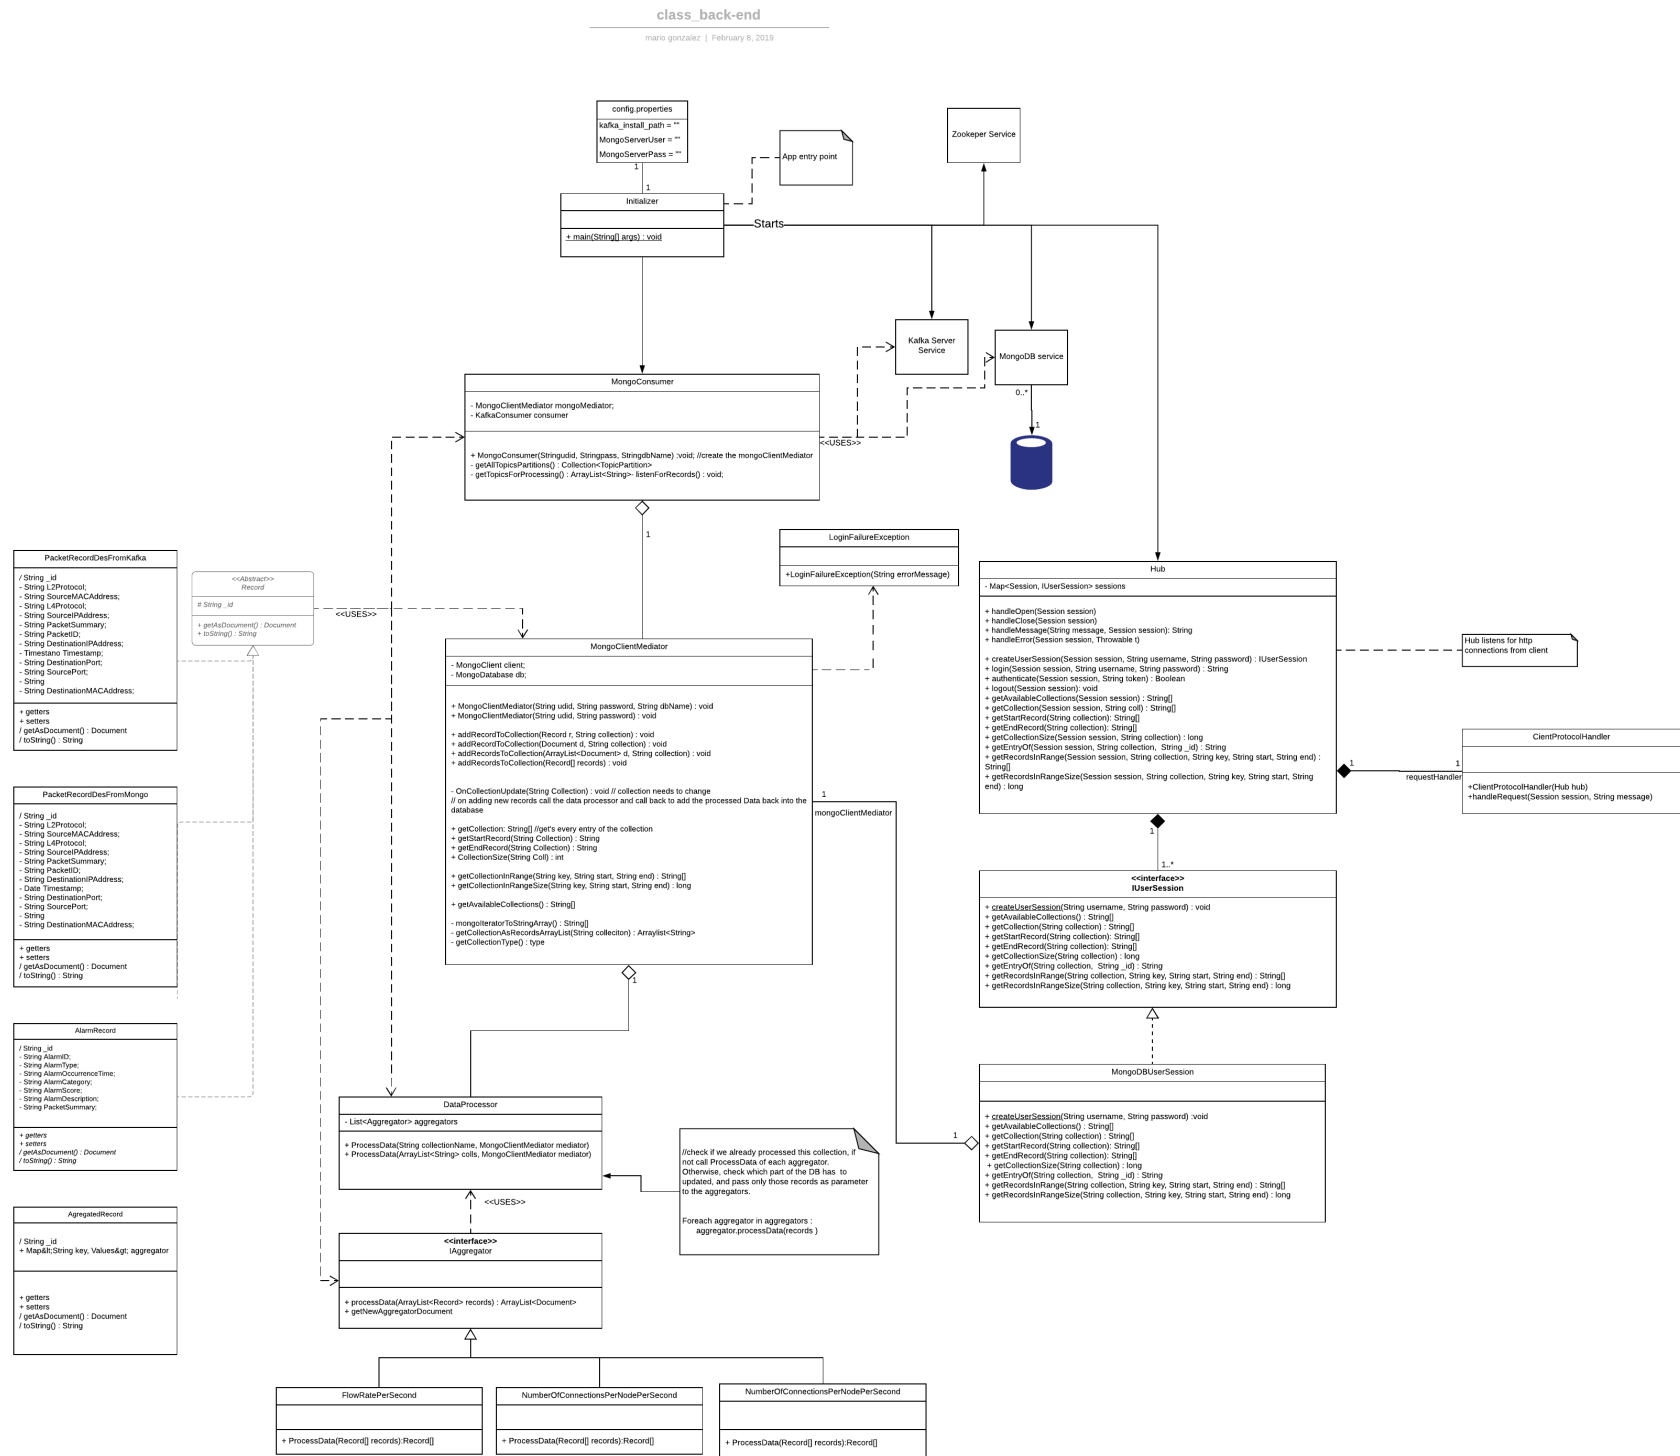

Figure 21: This is the class diagram for the whole back-end system

3.2 Sequence Diagrams

Figure 22 shows the initalization sequence order, the correspoding class diagram is Figure 18, the program dependes on a couple of services namely (in order), the zookeeper serivce, the kafka server service and the mongoDB service. Once all services are up and running the MongoConsumer is created and can start consuming messages and the Hub can start listening to client logins, requests, etc.

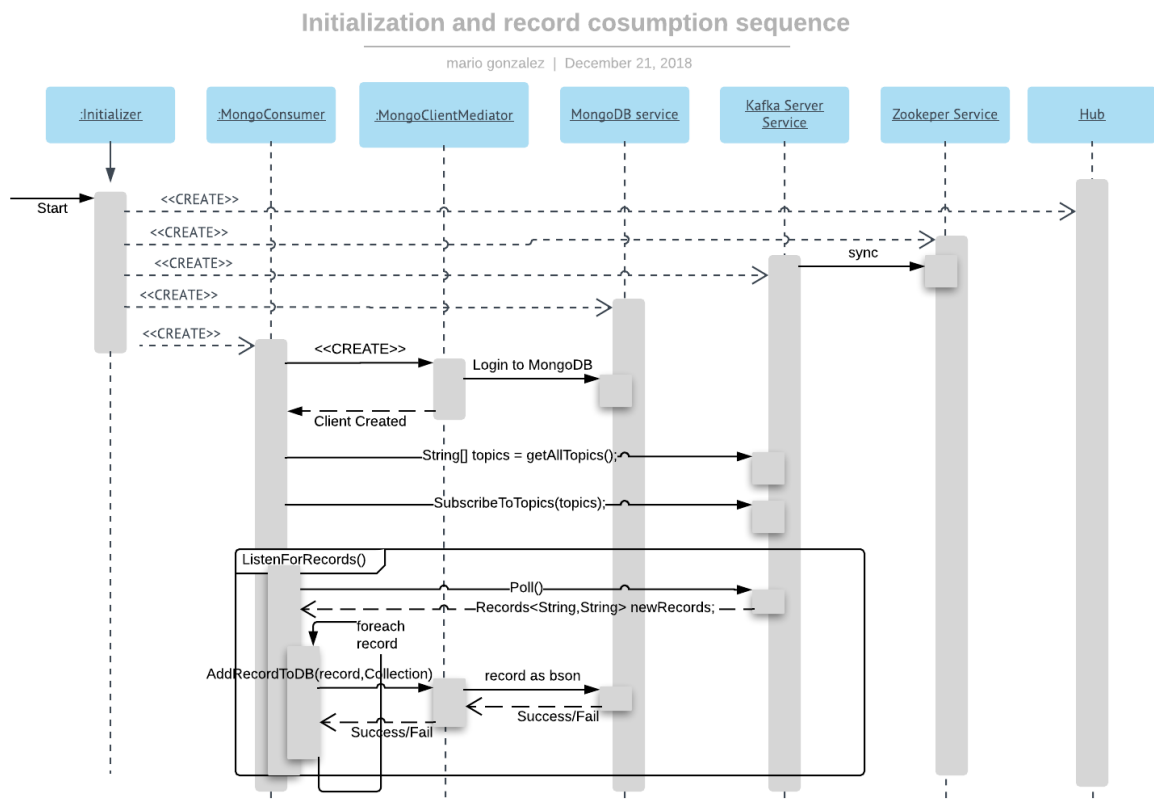

Figure 22: Initialization sequence and message consumption

3.3 Activity Diagram

As previously mentioned for UAC the built-in UAC in MongoDB is used.
Figure 25 shows the workflow on adding new roles and new user, who upon creation have a role assigned to them, to MongoDB.
A Role determines what can be done and seen within a database. For the purposes of the ADIN INSPECTOR there are three basic roles, Admin, Operator and Analyst. The admin role , created by default, can create and destroy users as well as assign specific roles to them. An analyst can see all collections on the database and an Operator can only see part of them.
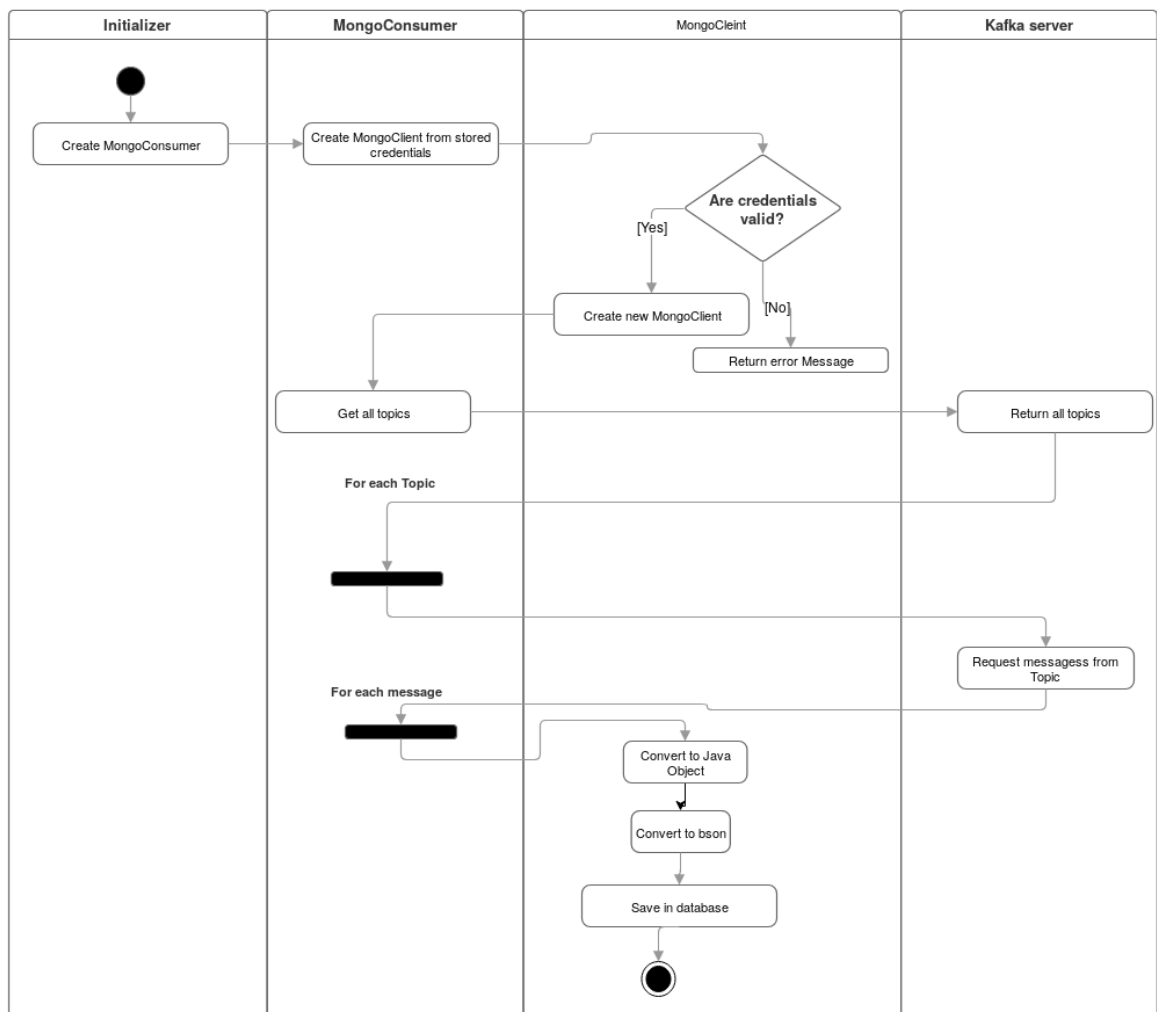

Figure 23: Initialization and message consumption workflow.

Figure 24: This diagram shows the processing of Collections and records as well as the addition of extracted data back into the database.
Figure 25: User Management workflow

4 Changes

Changes made between version 1.1.0 and version 2.0.0 of this document.

4.1 Changes to the document

- Move all (sub-)sections one numbering level up.

4.2 Changes to the front-end

- Update the login screen: add input field for server url.

4.3 Changes to the client-server protocol

The protocol responses have been made more expressive in general.

- Rename "LOGIN_TOKEN" request to "AUTH".

- Rename "LIST_COL" response to "LIST_COLL".

- Expand "session" response with the specifier key "par"

- Expand "data set" and "collection size" responses with the key "key"

- Expand "data set" and "collection size" responses with the keys "start" and "end", if they were in the request

- "data set" and "collection size" responses will now echo back any key-value pairs not specified in the protocol

- getStartRecord, getEndRecord, and the "single data point" response were added. itemgetEndpoints and the "data endpoints" response were added.

4.4 Changes to the back-end

- Added new aggregator class AddressesAndLinks

- Added class LoginFailureException

- Rename class PacketRecord to PacketRecordDesFromKafka, changed the type of timestamp

- Added class PacketRecordDesFromMongo

- MongoClientMediator: added variants of methods addRecordToCollection() and addRecordsToCollection() to handle Records and bson Documents.

- MongoClientMediator: added new method getTopicsForProcessing().

- Hub: methods login(), authenticate() and logout() were added.
